Algorithm

1. Start.
2. Read the number of stops and routes.
3. Build a weighted adjacency list from the route data.
4. Read and validate the source stop.
5. Set all distances to infinity and set the source distance to zero.
6. Insert the source into a min-priority queue with distance zero.
7. While the queue is not empty, remove the stop with the smallest distance. Skip outdated entries.
8. For each neighbor, if the current route gives a shorter distance, update the neighbor's distance and insert it into the queue.
9. Display the minimum travel time to each stop. For a stop whose distance remains infinity, display "Unreachable".
